⑥④ **Multiple-Load cartridge assembly for a linear surgical stapling instrument.**

⑥⑦ A multiple-load cartridge assembly for use with a linear surgical stapling instrument of the type which, when actuated, simultaneously implants at least one row of staples in the tissue of a patient and forms or clinches the staples of the row against the instrument anvil. The cartridge assembly comprises a cartridge having a row of staple-containing forming pockets and a driver having a plurality of blades equal in number to the number of forming pockets and configured to drive the staples from the forming pockets through the tissue to be sutured and against the instrument anvil to be clinched, when the surgical stapling instrument is actuated. The cartridge has at least one row of storage pockets, equal in number to the forming pockets, and each containing at least one staple. An indexing mechanism is provided to shift the at least one staple in each storage pocket to the line of action between the driver and the anvil after the first actuation of the surgical stapling instrument, for at least another actuation of the surgical stapling instrument. A safety interlock within the cartridge assembly assures correct sequential operation of the cartridge assembly and prevents jamming thereof. An indicator visually shows the number of the load of staples ready to be implanted and formed.

EP 0 156 774 A2

MULTIPLE-LOAD CARTRIDGE ASSEMBLY
FOR A LINEAR SURGICAL STAPLING INSTRUMENT

Ronald J. Brinkerhoff

Rudolph H. Nobis

TECHNICAL FIELD

The invention relates to a cartridge assembly for a linear surgical stapling instrument, and more particularly to such a cartridge assembly containing more than one load of surgical staples, thereby enabling the surgical stapling instrument to be actuated more than once before changing surgical stapling instruments or reloading or replacing the cartridge.

BACKGROUND ART

In recent years, there has been an increasing number of surgeons using surgical staples, rather than conventional sutures. This is true because the use of surgical staples and surgical stapling instruments has rendered many difficult procedures much simpler. Of even more importance, however, is the fact that the use of surgical staples significantly reduces the time required for most procedures and, therefore, reduces the length of time for which the patient must be maintained under anesthetic.

Many types of surgical stapling instruments have been devised for many different procedures. The present invention is directed to a linear surgical stapling instrument. This is an instrument which, on a single actuation, simultaneously implants and forms at least one rectilinear row of surgical staples. Such instruments are used on many different organs and tissues, such as the lung, the esophagus, the stomach, the duodenum, and throughout the intestinal tract.

In its earliest form, the linear surgical stapling instrument was a permanent, multi-use instrument, and the surgical staples were manually loaded into the instrument one-by-one. An exemplary surgical stapling instrument of

1 this type is taught in U.S. Patent No. 3,080,564. While
such instruments performed well, they were, in general,
complex in construction, expensive to manufacture, heavy,
bulky and difficult both to load with surgical staples
5 and to clean and sterilize after each use.

A significant improvement in the linear surgical
stapling instrument came about with the provision of pre-
sterilized, disposable loading units or staple cart-
ridges. U.S. Patent No. 3,275,211 and U.S. Patent No.
10 3,589,589 are exemplary of those relating to permanent,
multi-use, linear instruments having replaceable staple
cartridges. While this improvement significantly reduced
the time previously required for hand-loading of the
staples, the basic instrument still had to be disassem-
15 bled, cleaned, reassembled and sterilized for each proce-
dure, and frequently required additional maintenance and
adjustment. Also, if more than one load of staples was
required in a given procedure, the cartridge had to be
replaced each time, as it contained only a single load.

20 Even more recently, in view of rising hospital costs,
there has been an ever increasing interest in disposable
surgical stapling instruments, to eliminate as much work
as possible (i.e., disassembling, cleaning, reassembling,
sterilization and the like) and to be more efficient,
25 while at the same time not having to compromise the surgi-
cal procedures.

Such a disposable linear surgical stapling instrument
is taught, for example, in co-pending application Serial
No. 06/503,231, filed June 10, 1983, in the names of
30 Hector Chow and Hugh Melling, and entitled "DISPOSABLE
LINEAR SURGICAL STAPLING INSTRUMENT". This instrument,
simple in construction and relatively inexpensive to manu-
facture, is characterized by a working gap or range of
distances between the instrument anvil and the cartridge
35 over which a single size staple can be properly implanted

1 and formed. The proper and desired setting of the instru-
ment, within the working gap, is easily accomplished
through simple manipulation of an adjustment knob at the
rear of the instrument with indicator means on each side
5 of the instrument to clearly show when the distance
between the anvil and the cartridge is within the working
gap. In addition, the gap to which the instrument is set
can fall anywhere within the confines of the working gap
of the instrument. The instrument is provided with an
10 alignment and retaining pin, shiftable to an operable
position wherein alignment between the anvil and the
staple cartridge is ensured, and wherein tissue to be
sutured, located between these elements, is retained
therebetween. The instrument is provided with a lockout
15 device which precludes rotation of the adjustment knob to
secure the desired gap unless the alignment and retaining
pin has been shifted to its operative position. The
instrument is also provided with a novel trigger safety
which will disable the trigger until the movable jaw of
20 the instrument has been shifted to a position near the
working gap.

For purposes of economy and simplicity, much of the
instrument is made of appropriate plastic material, while
most of the major load-bearing elements of the instrument
25 are metallic. The instrument is so designed that the
staple driver is coupled to the trigger at all times. As
a result of this, the driver is not free floating and
cannot accidentally dislodge or discharge the surgical
staples during shipping and handling prior to use of the
30 instrument in the operating room.

As indicated above, linear surgical stapling instru-
ments (whether they be permanent, reusable instruments or
disposable, single-use instruments) are characterized by
the fact that they simultaneously form and implant at
35 least one rectilinear row of surgical staples. In fact,

1 the most commonly encountered linear surgical stapling
instrument simultaneously forms and implants two recti-
linear rows of surgical staples, with the surgical
staples of one row being offset or staggered with respect
5 to the surgical staples of the other row. This assures
reliable suturing of the tissue to be joined together.

It has been found that it would be a matter of great
convenience to the surgeon if the staple cartridge would
contain more than one load of surgical staples. The word
10 "load" used here and hereinafter refers to that number of
staples required to make up the single or double row of
staples implanted when the surgical stapling instrument
is actuated. This would enable the surgeon to perform
two or more suturing procedures before changing cart-
15 ridges in a permanent or disposable multiple-use instru-
ment or changing instruments in the case of a disposable
instrument.

As a consequence, the present invention is directed
to a multiple-load cartridge assembly for a linear surgi-
20 cal stapling instrument. Depending upon the materials
from which the elements of the cartridge of the present
invention are made and the manner in which they are assem-
bled, the cartridge may be provided in a number of forms.
For example, the cartridge can constitute a reusable,
25 refillable cartridge to be used with a permanent, non-
disposable linear surgical stapling instrument. The
cartridge can be a replaceable and disposable cartridge
for a permanent instrument. The cartridge can be a
reusable, refillable cartridge for a disposable instru-
30 ment. The cartridge can be a replaceable and disposable
cartridge for a disposable instrument. Finally, the
cartridge can constitute a permanent part of a disposable
instrument, the instrument and cartridge being disposed
of when the cartridge is empty.

1 DISCLOSURE OF THE INVENTION

 According to the invention, there is provided a multiple-load cartridge assembly for use with a linear surgical stapling instrument of the type which, when
5 actuated, simultaneously implants at least one row of staples in the tissue of a patient, and forms or clinches the staples of the row against the instrument anvil.

 In its simplest form, the cartridge assembly comprises a cartridge having at least one row of staple-
10 containing forming pockets and a driver having a plurality of blades equal in number to the number of forming pockets. The driver blades are configured to drive the staples from the forming pockets through the tissue to be sutured and against the tool anvil to be clinched, when
15 the surgical stapling instrument is actuated. The cartridge also has a plurality of storage pockets, equal in number to the forming pockets and each containing one staple. After the first actuation of the surgical stapling instrument, an indexing mechanism, mounted within
20 the cartridge, shifts the staple in each storage pocket into the adjacent forming pocket, to reload the forming pockets for another actuation of the surgical stapling instrument. An interlock may be located within the cartridge and prevents actuation of the indexing mechanism
25 until the forming pockets have been cleared of the first staple load. In this way, correct sequential operation of the cartridge is assured and jamming of the cartridge is precluded.

 In a second embodiment of the invention, each storage
30 pocket may contain a plurality of surgical staples arranged one behind the other in a row extending perpendicular to the driver. Upon each actuation of the driver and return thereof to its retracted position, an indexing member shifts a staple from each storage pocket to each
35 forming pocket. A third embodiment is similar to the

1 second embodiment with the exception that each row of
staples in each storage pocket extends diagonally with
respect to the driver.

5 In a fourth embodiment, a staging pocket is located
between each holding pocket and each forming pocket. An
indexing mechanism is provided to shift a staple from the
storage pocket to the staging pocket. A second indexing
mechanism is provided to shift a staple from the staging
10 pocket to the forming pocket. In yet another embodiment
having a storage pocket and a staging pocket for each
forming pocket, the staples are stacked one above the
other in the storage pocket and are fed automatically by
spring means or the like into the staging pocket. An
indexing mechanism is provided to shift a staple from the
15 staging pocket to the forming pocket.

To demonstrate the application of the present inven-
tion to an existing linear surgical stapling instrument,
there is taught herein an embodiment of the cartridge of
the present invention constituting a permanent part of a
20 disposable linear surgical stapling instrument of the
type described in the above noted co-pending application.
The cartridge contains two loads of staples and the
linear surgical stapling instrument is capable of two
actuations, forming and implanting two staggered rows of
25 surgical staples with each actuation of the instrument.
Thereafter, the instrument and its cartridge are disposed
of. The cartridge assembly comprises a cartridge having
two staggered parallel rows of forming pockets and a stor-
age pocket for each forming pocket. Each forming pocket
30 and each storage pocket contains one surgical staple. A
driver is provided having a driving blade for each form-
ing pocket. The cartridge assembly is provided with a
casing which is mounted on the cartridge with a support
plate therebetween. The driver is mounted within the
35 casing, with its driving blades extending through the

1 support plate and into the cartridge.

A slider is provided for each row of storage pockets. The sliders are actuated by a manual indexing button slidably mounted in the casing. When the button is manually shifted, it will shift the sliders which, in turn, will index the staples in the storage pockets into their respective forming pockets. A safety is provided to preclude actuation of the indexing button until the linear surgical stapling instrument has been once actuated to clear the forming pockets of their first staple load. Thereafter, when the driver is returned to its normal retracted position, the indexing button can be shoved inwardly with respect to the casing, causing the sliders to shift the staples in the storage pockets into their respective forming pockets, providing a second load of staples in the forming pockets and enabling a second actuation of the instrument.

In another embodiment of the invention, one or more sets of storage pockets, each containing one staple, are provided and are arranged identically to the forming pockets. The first set of forming pockets and all the sets of storage pockets are movable with respect to the instrument centerline through any appropriate path of travel (rectilinear, arcuate, etc). After the first actuation of the instrument, which clears the first forming pockets, and when the driver is retracted, the at least one more set of storage pockets can be moved into alignment between the driver and the anvil, displacing the first set of empty forming pockets. These storage pockets thus become forming pockets to allow for at least another actuation of the instrument.

BRIEF DESCRIPTION OF THE DRAWINGS

Figures 1-4 are diagrammatic representations, partly in cross-section, of a double-load embodiment of the cartridge assembly of the present invention, illustrating its

1 sequential operation.

Figures 5-8 are diagrammatic representations, partly in cross-section, of a multiple-load embodiment of the cartridge assembly of the present invention, illustrating its sequential operation.

Figures 9-12 are diagrammatic representations, partly in cross-section, illustrating an embodiment similar to that of Figures 5-8, with the row of staples in each storage pocket extending diagonally with respect to the driver.

Figures 13-16 are diagrammatic representations, partly in cross-section, of another embodiment having a staging pocket between each storage pocket and forming pocket, and illustrating the sequence of operation thereof.

Figures 17-20 are diagrammatic representations, partly in cross-section, illustrating an embodiment of the present invention similar to that of Figures 13-16, but having a vertical stack of staples in each storage pocket and automatic means to feed staples from each storage pocket to each staging pocket, and further illustrating the mode of operation of this embodiment.

DETAILED DESCRIPTION OF THE INVENTION

 Figures 1-20 are simplified diagrammatic representations illustrating the basic concepts of the cartridge assembly of the present invention.

20 Reference is first made to Figure 1, wherein a cartridge assembly is generally indicated at 1. The anvil of a linear surgical stapling instrument is diagrammatically indicated at 2. The cartridge 1 is provided with a plurality of forming pockets, one of which is shown at 3. A staple 4 is located within the forming pocket 3. It will be understood that, as viewed in Figure 1, the forming pockets 3 will be located one behind the other in a linear row. Each will contain a staple equivalent to staple 4, so that the staples, themselves, will be arranged in a linear row.

30 A staple driver is shown at 5. The staple driver is provided with a blade for each forming pocket, the blades being slidably mounted in their respective forming pockets. The blade for forming pocket 3 is shown at 6.

1 A storage pocket 7 communicates with the upper end of
forming pocket 3. It will be understood that there will
be a similar storage pocket for each forming pocket.
Storage pocket 7 contains a staple 8, as will all of the
5 other storage pockets. An indexing mechanism is indicated at 9. In this diagrammatic representation, the indexing mechanism is illustrated as having a plunger-like element for each storage pocket. The plunger-like element of indexing mechanism 9 for storage pocket 7 is
10 shown at 10.

To complete the structure, a vertical slot is shown at 11. The vertical slot 11 contains a safety 12 slidably mounted therein. There may be a vertical slot 11 and safety 12 for each set of forming pockets and storage
15 pockets. Alternatively, the slot 11 may run longitudinally throughout the length of cartridge assembly 1 with the safety 12 also extending the full length of the cartridge assembly 1. A window 13 may be provided, communicating with the lower end of slot 11.

20 Figure 1 illustrates the cartridge assembly 1 in its initial fully loaded condition. It will be understood that the cartridge assembly 1 will be mounted on a linear surgical stapling instrument (not shown). The operation of cartridge assembly 1 will be described in terms of
25 forming pocket 3, storage pocket 7 and staples 4 and 8. It will be understood that precisely the same things will occur in all of the forming pockets and storage pockets.

When the linear surgical stapling instrument (not shown) is actuated for a first time, the driver 5 will be
30 shifted downwardly to the position shown in Figure 2. This will drive staple 4 through tissue (not shown) located between the cartridge assembly 1 and anvil 2, and will cause the staple 4 to be formed by anvil 2. At the same time, the safety 12, which when in the position
35 shown in Figure 1 precluded actuation of index mechanism

1 9, is shifted downwardly in slot 11 by driver 5.

After the first actuation of the linear surgical stapling instrument, the driver 5 is withdrawn to its normal retracted position. With the safety 12 located in the
5 bottom of slot 11, the indexing mechanism 9 is free to be actuated, shoving staple 8 from storage pocket 7 into forming pocket 3, as illustrated in Figure 3. When the indexing mechanism 9 is returned to its normal retracted position, as shown in Figure 4, the staple 8 is free to
10 be implanted and formed by a second actuation of the linear surgical stapling instrument, in the same manner described with respect to staple 4 in Figure 2.

The window 13 provides a visual indication to the surgeon that the cartridge assembly 1 is ready for the first
15 actuation of the linear surgical stapling instrument or the second actuation of the linear surgical stapling instrument. This can be accomplished in several ways. The inside of slot 11 may be provided with one color and the safety with another. Similarly, the inside surface
20 of slot 11 may be provided with indicia viewable through window 13 and the safety 12 may be provided with additional indicia viewable through window 13. Both colors and indicia, viewable through window 13, can be used. The cartridge assembly 1 of Figures 1-4 constitutes a
25 simple example of a two-load cartridge assembly.

An exemplary multiple-load cartridge assembly is illustrated diagrammatically in Figures 5-8. In this instance, the cartridge assembly is generally indicated at 14 and is shown in cross-section through one side of
30 the cartridge (i.e., one set of forming pockets and storage pockets). A forming pocket is shown at 15 and its respective storage pocket is shown at 16. A driver 17, similar to driver 5 of Figure 1, is shown, together with its blade 18 for forming pocket 15. An indexing
35 mechanism 19, similar to indexing mechanism 9 of Figure 1

1 is shown, provided with its plunger-like portion 20 for
storage pocket 16. The anvil of the linear surgical
stapling instrument (not shown) to which cartridge
assembly 14 is attached is indicated at 21.

5 Figure 5 illustrates the cartridge assembly 14 in its
initial unfired condition. A staple 22 is located in
forming pocket 15 and three additional staples 23, 24 and
25 are located within storage pocket 16. Figure 6 illus-
10 trates the cartridge assembly 14 after the linear surgi-
cal stapling instrument (not shown) has been actuated for
a first time. This results in driver 17 and its blade 18
forcing surgical staple 22 through tissue (not shown)
located between cartridge assembly 14 and anvil 21, and
clenching the surgical staple 22 against anvil 21. It
15 will be understood that all of the other staples (not
shown) in all of the other forming pockets (not shown)
will be similarly implanted and formed.

At the end of the first cycle of the linear surgical
stapling instrument, the driver 17 will be returned to
20 its normal retracted position, as shown in Figure 7. At
this point, the indexing mechanism 19 will shift all of
the next staples 23 in each of the storage pockets 16
into their respective forming pockets 15. This is shown
in Figure 8, wherein the first staple 23 of storage
25 pocket 16 has been shifted into forming pocket 15. The
linear surgical stapling instrument (not shown) can be
actuated for a second time. This will result in implant-
ing and forming or clenching of staple 23. This same
procedure can be repeated through the implanting and
30 clenching of staple 25, at which point the cartridge
assembly 14 is empty and may be refilled or disposed of,
depending upon whether it is a refillable and reusable
cartridge assembly or a disposable cartridge assembly.

Figures 9-12 diagrammatically illustrate another
35 embodiment of cartridge assembly similar to that shown in

1 Figures 5-8. Like parts have been given like index numer-
als. Cartridge assembly 14a differs from cartridge assem-
bly 14 of Figures 5-8 only in that the storage pocket 16a
lies at an angle to the forming pocket 15. The plunger-
5 like portion 20a of indexing mechanism 19 is appropri-
ately configured to advance staples 23-25 in the storage
pocket 16a. It will be apparent from Figures 9-12 that the
operation of cartridge assembly 14a is substantially
10 identical to that described with respect to the cartridge
assembly 14 of Figures 5-8. Figures 9-12 illustrate that
variations can be made in the geometry and/or motions
within the cartridge assembly of the present invention.

Another embodiment of the cartridge assembly of the
present invention is diagrammatically illustrated in
15 Figures 13-16. Again, it will be understood that the
cartridge assembly, generally indicated at 26, will be
attached to a linear surgical stapling instrument (not
shown) having an anvil 27. Again, the views 13-16 are
cross-sectional views through one side of the cartridge,
20 illustrating one of a plurality of forming and storage
pockets. The forming pocket is shown at 28. The storage
pocket is shown at 29.

A driver 30, equivalent to driver 5 of Figure 1, is
provided having a blade for each forming pocket. The
25 blade for forming pocket 28 is shown at 31. A first
indexing mechanism 32 is provided with a plunger-like
portion for each storage pocket.. The plunger-like por-
tion for storage pocket 29 is shown at 33.

The embodiment of Figures 13-16 differs from the
30 previously described multiple-load cartridge assemblies
in that a staging pocket is provided between each storage
pocket and forming pocket. The staging pocket between
forming pocket 28 and storage pocket 29 is shown at 34.

The indexing mechanism 32 comprises a first indexing
35 mechanism adapted to shift a staple from storage pocket

1 29 to staging pocket 34. A second indexing mechanism is
provided and is indicated at 35. The purpose of the
second indexing mechanism 35 is to shift a staple from
the staging pocket 34 to forming pocket 28. As in the
5 case of the first indexing mechanism 32, indexing mechanism 35 will have a plunger-like portion 36 for each staging pocket of the cartridge assembly 26.

It will be noted in Figure 13 that a first staple 37
is located in forming pocket 28. Storage pocket 29 contains three additional staples 38, 39 and 40. Storage
10 pocket 29 also contains a pusher 41 actuated by a compression spring 42.

In Figure 13, the cartridge assembly 26 is shown in its initial, fully loaded condition. A first actuation
15 of the linear surgical stapling instrument (not shown) will cause driver 30 to force staple 28 through tissue (not shown) located between the cartridge assembly 26 and the anvil 27 and to clinch staple 28 against anvil 27.
At the same time, the first indexing mechanism 32 shifts
20 the first staple 38 of storage pocket 29 into staging pocket 34. In fact, the first indexing mechanism 32 could be actuated by driver 30. To this end, driver 30 is shown in Figure 13 as having a lug (shown in broken lines) 30a overlying first indexing mechanism 32, which
25 will actuate indexing mechanism 32 when driver 30 is actuated.

After the first actuation of the linear surgical stapling instrument, driver 30 is returned to its normal retracted position, as shown in Figure 15. At the same
30 time, first indexing mechanism 32 is returned to its normal retracted position. This enables the pusher 41 and coil spring 42 to shift the next surgical staple 39 beneath the first indexing mechanism 32. At this stage, the second indexing mechanism 35 can be used to shift the
35 second staple 38 from the staging pocket 34 to forming

1 pocket 28. Thereafter, the second indexing mechanism 35
is returned to its normal position as shown in Figure 16
and the cartridge assembly is ready for the next actua-
tion of the linear surgical stapling instrument. This
5 series of steps may be continued until the last staple 40
of cartridge assembly 26 has been implanted and formed.

Another embodiment of the present invention is illus-
trated in Figures 17-20. The embodiment of Figures 17-20
is similar to that of Figures 13-16 and again demon-
10 strates how variations in geometry and/or motions within
the cartridge assembly can be made.

Turning first to Figure 17, the cartridge assembly is
generally indicated at 43 and is intended to be affixed
to a linear surgical stapling instrument (not shown)
15 having an anvil 44. As in the case of the embodiment of
Figures 13-16, the cartridge assembly 43 is provided with
a plurality of forming pockets, staging pockets and stor-
age pockets. In Figure 17, one set of these pockets is
illustrated. The forming pocket is shown at 45. The
20 staging pocket is indicated at 46 and the storage pocket
is shown at 47. The cartridge assembly 43 is provided
with a driver 48 having a blade for each forming pocket.
The blade for forming pocket 45 is shown at 49. As in
all of the embodiments, the cartridge assembly 43 aligns
25 the driver with respect to anvil 44. An indexing mechan-
ism 50 is provided having a plunger-like portion for each
staging pocket. The plunger-like portion for staging
pocket 46 is shown at 51. The indexing mechanism 50 is
equivalent to indexing mechanism 35 of Figure 13. In
30 Figure 17, a first staple is shown at 52 in forming
pocket 45. A second staple is shown at 53 in staging
pocket 46 and third and fourth staples are shown at 54
and 55 in storage pocket 47.

In the embodiment of Figure 17, the storage pockets
35 differ from those of the embodiment of Figure 13 in

1 several respects. First of all, the storage pocket 47 is
oriented parallel to the blade 49 of driver 48. The
surgical staples 54 and 55 are stacked in storage pocket
47 one above the other. The storage pocket is provided
5 with a pusher 56 actuated by a compression spring 57 and
guided in guideways 58 and 59. Thus, pusher 56 and com-
pression spring 57 automatically feed surgical staples
from the storage pocket 47 to staging pocket 46 without
the necessity of an additional indexing mechanism equiva-
10 lent to indexing mechanism 32 of Figure 13.

Figure 17 illustrates the cartridge assembly 43 in
its initial fully loaded condition, ready for the linear
surgical stapling instrument (not shown) to be actuated
for a first time. Upon actuation of the linear surgical
15 stapling instrument, the driver 48 forces the staple 52
in forming pocket 45 to pass through tissue (not shown),
located between the cartridge assembly 43 and the anvil
44, and to be clinched by the anvil 44. This is shown in
Figure 18.

20 After the first actuation of the linear surgical
stapling instrument, the driver 48 is returned to its
initial retracted position and indexing mechanism 50 may
be used to shift the second staple 53 from staging pocket
46 into forming pocket 45. This is shown in Figure 19.
25 Thereafter, the indexing mechanism 50 is returned to its
normal position as shown in Figure 20 and the third
staple 54 is shifted from storage pocket 47 to holding
pocket 46 by pusher 56 and compression spring 57. The
cartridge assembly 43 is now ready for a second actuation
30 of the linear surgical stapling instrument. These
sequential operations can be continued until the last
staple 55 of cartridge assembly 43 has been formed and
implanted.

In all of the embodiments of Figures 5-20, safety
35 interlocks and load counting means have been omitted for

purposes of clarity. It will be understood, however, that such elements could and preferably would be provided with each embodiment. It will be understood by one skilled in the art that efficient design of the cartridge design would allow for single inputs from the surgeon via the linear surgical stapling instrument to result in several motions within the cartridge. For example, the forward stroke of the driver could not only form staples, but could also transfer staples from the storage pockets to the staging pockets, as described with respect to the embodiment of Figures 13-16. Similarly, the driver could be spring loaded so that it returns upon release, and in so doing, staples could be shifted from the storage pockets (or staging pockets if present) to the forming pockets. It could be within the scope of the invention to provide some form of stored energy source, such as a battery or compressed gas, to partially or fully operate the cartridge assembly .

As has been disclosed above, the geometry and/or the motions within the cartridge assembly can be widely varied. The use of staging pockets, as is evident from the above, is optional.

In all of the embodiments of Figures 1-20, the driver may or may not be a part of the multiple load cartridge assembly, as desired. Similarly, the anvil could be a part of the cartridge assembly, or not, as desired.

As indicated above, the cartridge assembly of the present invention may be permanent and refillable or it may be a single-use, disposable assembly. For purposes of a complete disclosure, the teachings of the present invention will now be described as applied to an actual linear surgical stapling instrument. While not intended to be so limited, for purposes of an exemplary showing the cartridge assembly of the present invention will be described in its application as a permanent part of a

1 disposable linear surgical stapling instrument of the
type taught in the above-identified co-pending applica-
tion. The teachings of this co-pending application are
incorporated by reference herein, in their entirety.

5 A disposable linear surgical stapling instrument of
the type contemplated is illustrated in Figure 21 and is
generally indicated at 60. Briefly, the instrument 60
comprises a body 61 having a handle 62 and a trigger
assembly 63. The instrument is provided at its forward
10 end with a fixed jaw 64, supporting an anvil 65. The
instrument 60 is also provided with a movable jaw com-
prising the cartridge assembly of the present invention
and generally indicated at 66. The movable jaw 66 is
shiftable mounted on the body 61 and is operatively
15 connected to the handle and trigger assembly 62-63.

An adjustment bolt (not shown) is slidably mounted
within the body 61 and is shiftable forwardly and rear-
wardly therein. An adjustment knob 67 is rotatably
mounted at the rearward end of the body 61. The adjust-
20 ment knob is operatively connected to the bolt to cause
the bolt to shift forwardly and rearwardly within body
61.

When the adjustment bolt is shifted forwardly within
the instrument body 61, by means of the adjustment knob
25 67, the bolt moves the handle and trigger assembly 62-63
forwardly and causes the movable jaw or cartridge assem-
bly 66 to approach the fixed jaw 64. In other words, the
cartridge assembly 66 approaches the anvil 65. A staple
driver (not shown) is located in association with cart-
30 ridge assembly 66 and is connected to and is shiftable by
trigger 63 to drive staples from the cartridge assembly,
through tissue (not shown) to be sutured (located between
the cartridge assembly 66 and the anvil 65), and against
the anvil 65. The anvil has a plurality of anvil pockets
35 (not shown) configured to clinch the staples over a range

1 of distances between the anvil 65 and the cartridge assem-
bly 66, constituting the "working gap" of the instrument.
The adjustment bolt also actuates indicator means 68
located on each side of the instrument 60, clearly show-
5 ing when the working gap has been achieved between the
anvil 65 and the cartridge assembly 66. The indicator
means 68 is such that it will assist the surgeon in
adjusting the distance between the anvil 65 and the cart-
ridge assembly 66 within the working gap of instrument
10 60.

An alignment pin 69 is shiftably mounted on the
instrument body 61, extending through cartridge assembly
66. The alignment pin is manually shiftable by handle
means 70 from its retracted position shown in Figure 21
15 to an operative position wherein it also extends into the
fixed jaw 64. In this way, the alignment pin 69 not only
assures that the anvil 65 and cartridge assembly 66 are
properly oriented with respect to each other, but also
traps the tissue (not shown) to be sutured between the
20 anvil 65 and the cartridge assembly 66.

Figure 22 is an exploded view of the cartridge assem-
bly 66 of Figure 21. The cartridge assembly 66 is made
up of a cartridge 71, a driver 107, first and second
sliders 113 and 114, a support plate 126, an indexing
25 button 162, a casing 140 and a safety 172. Each of these
elements will be described in detail.

The cartridge 71 is shown in Figures 23 through 32,
wherein like parts have been given like index numerals.
Cartridge 71 comprises an integral, one-piece molded
30 plastic member comprising an elongated body 72, having a
bottom 73 and an upstanding surrounding wall or flange 74
extending along its longitudinal edges and about its end
75. At its end 76, the wall 74 slopes downwardly to the
bottom 73, as at 77 and 78.

35 Along one of its longitudinal flights, the wall 74

1 has, on its inside surface, a plurality of integral,
inwardly extending cam members 79. In similar fashion,
along the other of its longitudinal flights, the wall 74
has, on its inside surface, a second series of integral
5 cam members 80. As will be most apparent from Figures 24
and 29, the cam members 79 are substantially identical,
as are the cam members 80. Additionally, the cam members
79 and 80 are substantially identical. It is to be
noted, however, that the cam members 80 are staggered
10 with respect to the cam members 79 and, as a result, the
cam members 80 are one less in number than the cam mem-
bers 79.

The number of cam members 79 and 80 is not a limita-
tion on the present invention. For convenience, the cam
15 members 79 and 80 have been shown equal in number to the
slots forming the storage and forming pockets described
hereinafter.

Reference is made to Figure 29. It will be noted
that each cam member 79 has a first planar surface 79a
20 lying at an angle to wall 74 and extending away there-
from, a second surface 79b parallel to the inside surface
of wall 74 and a third surface 79c extending from surface
79b to the inside surface of wall 74. Each cam member 80
has wall surfaces 80a, 80b and 80c, equivalent to the
25 wall surfaces 79a through 79c of cam members 79. The
purpose of cam members 79 and 80 will be apparent herein-
after.

Near the end 75 of cartridge 71, the bottom 73 has a
perforation 81. The perforation 81 is adapted to accommo-
30 date alignment and retaining pin 69 (see Figure 21).
Near its other end 76, the bottom 73 of cartridge 71 has
an elongated slot 82. The slot 82 is adapted to accommo-
date the shank of the instrument pilot 82a (see Figure
45). The pilot 82a comprises a part of fixed jaw 64 and
35 has a shank lying at 90° to anvil 65 and passing through

cartridge 71 to render the cartridge captive and slidable with respect to instrument 60. The pilot 82a is fully described in the above noted co-pending application.

The outside surface of what has been termed, for convenience, the "bottom 73" of cartridge 71 is, in reality, the forwardmost surface of the cartridge assembly 66 and faces anvil 65 (see Figure 21). Near its end 75, the exterior surface of bottom 73 is provided with a forwardly extending spacer element 83 adjacent to perforation 81, as is shown in Figure 25. Similarly, the outside surface of bottom 73, near cartridge end 76, is provided with a forwardly extending spacer element 84 extending partway about the outermost end of slot 82. The spacers 83 and 84 cooperate with anvil 65 (see Figure 21) to determine the forwardmost position of cartridge assembly 66.

Referring now to Figure 26, cartridge 71 is provided with a centrally located, longitudinally extending, upstanding interior wall, generally indicated at 85. The wall 85 is provided with a plurality of vertical slots 86 which divide the wall 85 into alternating narrow upstanding elements 87 and wide upstanding elements 88. The endmost wide elements 88a and 88b are slightly narrower than the remaining wide elements 88 and are notched at their outermost edges, as at 88c and 88d, as is shown in Figure 28.

Referring again to Figure 24, the interior wall 85 separates two rectilinear rows of slots 89 and 90. All of the slots 89 are identical, as are all of the slots 90. The slots 90 are mirror images of slots 89. It will be noted from Figure 24 that the slots 90 are staggered with respect to the slots 89 and, therefore, are one less in number. The number of slots 89 and 90 does not constitute a limitation of the present invention.

A typical slot 89 is illustrated in Figure 24a. The

1 slot 89 in the cartridge bottom 73 is defined by a recti-
linear outer wall 89a, a pair of rectilinear end wall
portions 89b and 89c, a pair of arcuate end wall portions
89d and 89e, a pair of rectilinear end portions 89f and
5 89g similar to end wall portions 89b and 89c, a pair of
rectilinear inner wall portions 89h and 89i, parallel to
outer wall 89a, a pair of rectilinear inner wall portions
89j and 89k perpendicular to inner wall portions 89h and
89i, and a final inner wall portion 89l.

10 End wall portions 89b and 89c are so spaced from each
other that they will just nicely engage the legs of a
surgical staple with a frictional fit. The same is true
of rectilinear end wall portions 89f and 89g. As a
result, that portion of slot 89, defined by outer wall
15 89a and rectilinear end wall portions 89b and 89c, consti-
tutes a storage pocket generally indicated at 91. A sur-
gical staple is shown in storage pocket 91 in broken
lines at 92. In a similar fashion, the rectilinear end
wall portions 89f and 89g and the short rectilinear inner
20 wall portions 89h and 89i constitute a forming pocket,
the rectilinear end wall portions 89f and 89g being so
spaced from each other as to just nicely engage the legs
of a surgical staple with a frictional fit. The forming
pocket portion of slot 89 is generally indicated at 93
25 and a surgical staple is shown therein in broken lines at
94. The storage pocket portion 91 of slot 89 is sepa-
rated from forming pocket portion 93 by the shallow
arcuate end wall portions 89d and 89e which are camming
surfaces, as will be explained hereinafter. Inner wall
30 portions 89j, 89k and 89m constitute or define an
extended portion of slot 89 to accommodate a driver
blade, as will be apparent hereinafter.

In Figure 36, the slots 89 have all of their wall
portions 89a through 89m, together with their storage
35 pockets 91 and its forming pockets 93 shown. Also,

1 staples 91a are illustrated in storage pockets 91 and
staples 93a are shown in forming pockets 93. It will be
apparent from Figure 36 that all slots 89 have an outer
storage pocket provided with a surgical staple and an
5 inner forming pocket also provided with a surgical
staple. The same is true of all the slots 90, which are
simple mirror images of the slots 89. Each slot 90 will
have a storage pocket 94 equivalent to storage pocket 91
and a forming pocket 95 equivalent to forming pocket 93.
10 In each of the slots 90, a surgical staple 94a is shown
in storage pocket 94 and a surgical staple 95a is shown
in forming pocket 95.

Reference is now made to Figures 29, 30 and 31. As
is most clearly seen in Figure 29, vertical reinforcing
15 walls 98 extend perpendicularly from each portion of
bottom wall 73 which separates the adjacent slots 89.
Similarly, reinforcing walls 99 extend perpendicularly
from those portions of cartridge bottom 73 which separate
adjacent slots 90. As is apparent from Figures 24 and
20 29, each interior wall portion 88 will have one reinforcing
wall 98 and one reinforcing wall 99 constituting an
integral part thereof. Depending upon its position, each
interior wall portion 87 will have either one reinforcing
wall 98 or one reinforcing wall 99 constituting an inte-
25 gral part thereof. All of the reinforcing walls 98 are
identical, as are all of the reinforcing walls 99. The
reinforcing walls 99 are simple mirror images of reinforcing
walls 98. The tops of all of the reinforcing walls
98 and 99 are coplanar, as shown in Figure 30.

30 Referring to Figure 31, it will be apparent that each
wall 99 comprises a wide portion 99a adjacent one of the
inner wall portions 87 or 88, and portion 99a is of a
width such that its side walls are coplanar with the end
walls of each extension portion of adjacent slots 90.
35 Thus, the portions 99a of reinforcing walls 99 serve as

1 additional guides for the blades of driver 72, to be
described hereinafter. Each wall 99 has an additional
portion 99b adjacent the portion 99a and of lesser width.
5 This ensures that the wall 99 will not interfere with the
forming pockets 95 of slots 90. It will be remembered
that reinforcing walls 98 are a mirror image of reinforcing
walls 99 and are thus similarly configured.

Reference is now made to Figures 23 and 24. To complete the cartridge 71, it should be noted that the wall
10 74, at the cartridge end 75, has its interior surface so
configured as to provide an end surface 100 substantially
perpendicular to the long axis of interior wall 85. The
end surface 100 terminates in a pair of parallel surfaces
101 and 102, both perpendicular to end surface 100 and
15 both terminating in shoulders 103 and 104, respectively.
The purpose of the inner surfaces 100-104 of wall 74 will
be apparent hereinafter. At the other end 76 of cartridge 71, the interior surface of wall 74 is so configured
as to provide a pair of shoulders or surfaces 105
20 and 106. The purpose of these surfaces will be apparent
hereinafter.

The driver 107 will next be described, and reference
is made to Figures 33, 34 and 35. The driver 107 is an
integral, one-piece element comprising an elongated body
25 108, having at its ends hook-like elements 109 and 109a.
Extending from body 108, there are a plurality of blades
110, arranged in a rectilinear row. In similar fashion,
additional blades 111 extend from body 108. The blades
111 are also arranged in a rectilinear row. It will be
30 noted that the blades 111 are staggered with respect to
the blades 110 and, therefore, are one less in number.
It will further be noted that the blades 110 are equal in
number to the number of cartridge slots 89, while the
blades 111 are equal in number to the number of cartridge
35 slots 90.

As is most clearly shown in Figure 33, driver blades 110 and 111 are arranged in alternating groups of three. Starting at the left end of Figure 33, the first group comprises two blades 110 and one blade 111. The next group comprises two blades 111 and one blade 110, and so on. The blades of each group are joined together by webs 112 (see also Figure 35). As is evident from Figure 35, webs 112 are shorter than driver blades 110 and 111. Arranging the driver blades 110 and 111 in groups of three is a matter of convenience permitting cross bracing. Other groupings could be used. The webs 112 prevent spreading of driver blades 110 and 111 into the storage pockets 91 and 94.

Figure 36 is a simplified representation of the cartridge 71 and driver 107. In Figure 36, interior wall 85 of cartridge 71, together with cam elements 79 and 80 have been deleted for purposes of clarity. Figure 36 illustrates two groups of driver blades 110 and 111, and their connecting webs 112. It will be noted that the driver blades 110 are so positioned as to be centered over the staples 93a in forming pockets 93 of slots 89. Similarly, driver blades 111 are centered over the staples 95a in forming pockets 95 of slots 90. It will be appreciated from Figure 36 that when the driver is actuated, it will simultaneously drive the staples 93a and 95a from their respective forming pockets 93 and 95. Thus, two rows of staples, the staples of one row being staggered with respect to the other, will simultaneously be implanted in the tissue being sutured. It will be understood that the webs 112 extending between blades 110 and 111 will pass between the sections 87 and 88 of interior wall 85, through the slots 86 therebetween (see Figure 28).

As is most clearly shown in Figure 35, the free end of each driver blade 110 has a centrally located,

1 longitudinally extending slot 110a. Similarly, the free
end of each driver blade 111 has a centrally located,
longitudinally extending slot 111a. When the free ends
of driver blades 110 and 111 contact their respective
5 surgical staples 93a and 95a, the staple crowns will be
engaged in the longitudinal slots 110a and 111a. As is
most clearly shown in Figures 33 and 34, the longitudinal
slots 110a of driver blade 110 are interrupted at their
longitudinal centers by transverse notches 110b. Simi-
10 larly, the longitudinal slots 111a of driver blade 111
are interrupted at their longitudinal centers by trans-
verse notches 111b. As is known in the art, the trans-
verse notches 110b and 111b prevent staples from embed-
ding in the driver blades 110 and 111 should they be
15 over-formed.

Driver 107 is actuated by an elongated driver rod
(not shown) located within the body 61 of instrument 60
(see Figure 21). One end of the driver rod is opera-
tively connected to trigger 63. The other end of the
20 driver rod abuts the body 108 of driver 107 and is
engaged by the hook-like portions 109 and 109a (Figure
34), as described in the above noted co-pending applica-
tion.

Figure 22 illustrates a pair of sliders 113 and 114.
25 End views of sliders 113 and 114, as seen from the left
in Figure 22, are shown in Figures 37 and 38. It will be
evident from Figures 22 and 37 that slider 113 comprises
an elongated member, the outside surface of which is pro-
vided with a plurality of cam elements 115. The top sur-
face 116 is planar, as is bottom surface 117. The inside
30 surface 118 is also planar, oriented at 90° to bottom sur-
face 117. Top surface 116 is joined to inside surface
118 by a downwardly sloping surface 119. Slider 114 is
similarly configured, having a plurality of cam surfaces
35 120 on its outside surface, a planar top surface 121, a

1 planar bottom surface 122 and a planar inside surface 123
oriented at 90° to bottom surface 122. As in the case of
slider 113, the top surface 121 is joined to the inside
surface 123 by a downwardly sloping surface 124. As is
5 evident from Figures 22 and 45, sliders 113 and 114 are
substantially mirror images of each other, with the excep-
tion that slider 114 has one less cam element than slider
113, making their end configurations slightly different.
Nevertheless, sliders 113 and 114 are sufficiently simi-
10 lar that a detailed description of one will suffice for
the other. Reference is made to Figure 39 which is a
simplified fragmentary view of cartridge 71 (its inner
wall not shown) with slider 113 mounted therein.

In Figure 39, slider 113 is shown in its initial,
15 normal position. It will be noted that the cam members
115 of slider 113 are similar in configuration and nest
with the cam members 79 of the inside surface of cart-
ridge wall 74. Thus, each cam member has a surface 115a
equivalent to surface 79a, a surface 115b substantially
20 equivalent to that portion of the inside surface of wall
74 between cam members 79 and a surface 115c equivalent
to surface 79c. It will further be noted that the sur-
faces just described are just slightly spaced from each
other. Between cam elements 115, slider 113 has recti-
25 linear surfaces 125 adapted to abut the surfaces 79b of
cam elements 79. It will further be noted that the
planar inner surface 118 of slider 113 lies adjacent the
surgical staples 92 located in the storage pockets 91 of
slots 89.

30 Figure 40 illustrates what happens when slider 113 is
indexed in the direction of arrow A of Figure 39, such
that each cam member 115 of slider 113 shifts to the
other side of the next adjacent cam member 79 of cart-
ridge wall 74. It will be apparent from Figure 39 that
35 when slider 113 is shifted in the direction of arrow A,

1 cam surfaces 115a of the slider will contact and ride
along corresponding cam surfaces 79a of the cartridge
cams 79. Thus, slider 113 will not only move in the
5 direction of arrow A in Figure 39, it will also shift
inwardly toward the center of cartridge 71, to the posi-
tion illustrated in Figure 40. This longitudinal and
transverse movement of slider 113 will shift surgical
staples 91a from the storage pockets 91 to the forming
10 pockets 93 of slots 89. Thus, when the surgical staples
93a, originally located in forming pockets 93 of slots
89, have been implanted and clinched, the indexing of
slider 113, as described with respect to Figures 39 and
40, will shift staples 91a to forming pockets 93 so that
15 the instrument 60 can be actuated for a second time. It
will be apparent from Figure 39 that as the surgical
staples 91a shift from storage pocket 91 to forming
pocket 93, the legs of the staples 91a will have to bend
slightly toward each other to enable them to shift past
the arcuate end portions 89d and 89e of slots 89. When
20 the forming pockets 93 are reached, the staples 91a will
snap therein, being held by a frictional snap fit.

Slider 113 will remain in the position shown in
Figure 40. It will be apparent that in this position the
slider 113 will interfere with driver blades 110 (see
25 Figure 36). However, as the driver blades 110 descend,
they will first contact the beveled portion 119 of slider
113 which will cause the slider to shift toward cartridge
side 74 and its cam elements 79, out of the way of driver
blades 110.

30 It will be understood by one skilled in the art that
slider 114 operates in exactly the same manner to shift
staples 94a from storage pockets 94 of slots 90 to the
forming pockets 95 of the slots 90.

Support plate 126 is shown in Figures 22 and 41-44.
35 The support plate comprises an elongated member made up

1 of side walls 127 and 128, together with end walls 129
and 130. The side walls 127 and 128 narrow considerably
at 127a and 128a, adjacent the end 129. This narrowing
of the side walls creates a pair of shoulders 131 and
5 132, the purpose of which will be described hereinafter.
Side wall 127 has a pair of laterally extending lugs 133
and 134. Similarly, side wall 128 has a pair of later-
ally extending lugs 135 and 136. The purpose of lugs
133-136 will also be apparent hereinafter.

10 The inside surface of side wall 127 and its narrow
portion 127a has a plurality of inwardly extending lugs
137 and 137a thereon. The lugs 137a, of which there are
two, differ from lugs 137 only in that they extend above
the top surface of side wall 127 and its narrow portion
15 127a. In a similar fashion, the inside surface of side
wall 128 and its narrow portion 128a has a plurality of
lugs 138, 138a and 138b. The lugs 138a (of which there
are two) differ from lugs 138 in that they also extend
above the surface of side wall 128 and its narrow portion
20 128a. The endmost lugs 138b (adjacent end walls 129 and
130) are somewhat elongated as shown in Figure 41. To
complete the structure, it will be noted that end wall
130 is of lesser height than adjacent side walls 127 and
128, creating a notch 139. The purpose of notch 139 will
25 be described hereinafter.

Figure 45 illustrates the cartridge 71 with sliders
113 and 114 mounted therein, together with support plate
126. Mounting of the support plate is achieved by virtue
of the fact that all of the lugs 137 and 137a of side
30 wall 127 and its narrow portion 127a rest upon reinforc-
ing walls 98 of the interior wall 85. Similarly, all of
the lugs 138, 138a and 138b of support plate side wall
128 and its narrow portion 128a rest upon support walls
99 of the cartridge interior wall 85. End walls 129 and
35 130 of support plate 126 rest in the notches 88c and 88d

1 of cartridge interior wall endmost members 88a and 88b,
respectively. In addition, the exterior lugs 133 and 134
of side wall 127 rest upon selected ones of the cartridge
cam elements 79. In a similar fashion, the exterior lugs
5 135 and 136 of the support plate side wall 128 rest upon
selected ones of cartridge cam elements 80. As will be
made apparent hereinafter, the primary purpose of support
plate 126 is to serve as an interior reinforcing member
for the cartridge assembly 66. It will be understood
10 that the blades 110 and 111 of driver 107 will extend
through support plate 126.

The casing 140 is shown in Figures 22 and 46-51. The
casing 140, in cooperation with cartridge 71, encloses
the mechanism of the cartridge assembly 66. The casing
15 comprises a hollow, bottomless housing having substan-
tially planar side walls 141 and 142, a substantially
planar end wall 143 and an arcuate end wall 144. Side
walls 141 and 142 and end walls 143 and 144 have upwardly
and inwardly beveled portions 141a, 142a, 143a and 144a,
20 respectively, terminating in the planar casing top 145.

The casing top 145 has a longitudinal slot 146 and a
pair of transverse slots 147 and 148. The transverse
slot 147 extends through the beveled portion 141a and the
adjacent part of side 141. Similarly, the slot 148
25 extends through beveled portion 142a and the adjacent
part of side wall 142. The purpose of slots 146, 147 and
148 is to accommodate the driver rod and handle plates
(not shown) of the instrument. These elements are fully
described in the above noted co-pending application. The
30 top 145 also has a perforation 149 which is coaxial with
the perforation 81 of cartridge 71, and is also adapted
to accommodate alignment and retaining pin 69.

The arcuate end wall 144 of casing 140 has a notch
150 adjacent the open end of casing 140. Side walls 141
35 and 142 have notches 151 and 152, respectively, adjacent

1 the open end of casing 140 and near notch 150. Notches
150, 151 and 152 accommodate the indexing button of cart-
ridge assembly 66, as will be described hereinafter.

5 Adjacent notch 151, the interior surface of side wall
141 has a cavity 153 formed therein. This is shown in
Figures 50 and 51. That portion 141a of side wall 141
between notches 150 and 151 has the same thickness as the
cavity portion 153. In a similar fashion, side wall 142
10 has a cavity 154 formed on its inside surface adjacent
notch 152. That portion 142a of side wall 142 between
notches 150 and 152 is of the same thickness of the
cavity portion 154. Cavity portions 153 and 154 serve to
accommodate the indexing button of the cartridge assembly
66, as will be apparent hereinafter.

15 To complete the structure of casing 140, side wall
141 has a pair of shallow notches 155 and 156 adjacent
the open end of casing 140. Similarly, side wall 142
has, formed on its inside surface, shallow notches 157
and 158 near the open end of casing 140. When the casing
20 140 is mounted on cartridge 71, the interior notches 155
and 156 of side wall 141 will receive portions of the
lateral lugs 133 and 134, respectively, of support plate
126. Similarly, the interior notches 157 and 158 of side
wall 142 will receive portions of the lateral lugs 135
25 and 136 of support plate 126. The free edges of side
walls 141 and 142 will abut the walls 74 of cartridge 71.
That edge of planar end wall 143 of casing 140 adjacent
the open end of the casing will be received in the notch
130 at the end wall 139 of support plate 126. The abut-
30 ting surfaces of the cartridge 71 and casing 140 can be
joined together by any appropriate means, such as adhe-
sive means, sonic welding or the like. These abutting
edges may be given a ship-lap configuration, if desired.

Turning briefly to Figure 63, casing 140 is shown
35 mounted on cartridge 71. It will be noted that those

1 edges of casing sides 141 and 142 adjacent the open end
of the casing are in abutment with the surrounding wall
74 of cartridge 71. As indicated above, the engagement
of these edges could be a ship-lap engagement, and they
5 are joined together by any suitable means, such as adhesive,
sonic welding or the like. Since the cartridge
assembly is intended for use in a surgical environment,
sonic welding is frequently preferred. Figure 63 also
illustrates sliders 113 and 114, driver 107 and support
10 plate 126.

The handle plates of the instrument 160, fully
described in the above mentioned co-pending application,
are fragmentarily shown in Figure 63 at 160 and 161.
Handle plates 160 and 161 constitute part of the mechanism
15 by which a compressive force is applied to the tissue
located between the cartridge assembly 66 and anvil 65,
during achievement of the proper gap within the working
gap of the instrument, prior to the suturing or stapling
operation. One of the functions of support plate 126 is
20 to transmit the force from handle plates 160 and 161 to
the cartridge 71.

Referring to Figures 41-44, it will be remembered
that the lugs 137a and 138a extend above the side walls
of support plate 126. One pair of lugs 137a-138a is
25 shown in broken lines in Figure 63. The function of
these lugs is to maintain proper spacing between those
portions of handle plates 160 and 161 within the cartridge
assembly 66 to assure clearance between them and
driver 107. The other pair of support plate upstanding
lugs 137a and 138a, not shown in Figure 63, serve the
30 same purpose.

Figure 63 also illustrates the lateral lugs 155 and
157 of support plate 126, engaged in the notches 155 and
157, respectively, of the casing side walls 141 and 142.
35 It will be understood that support plate lugs 134 and 136

1 will similarly be engaged in casing notches 156 and 158,
respectively. As a result of this, support plate 126
contacts both the casing walls 141 and 142 and the
surrounding wall 74 of cartridge 71. It will further be
5 remembered that each of the support plate interior lugs
137 and 137a abut and are supported by reinforcing walls
98 while support plate lugs 138, 138a and 138b abut and
are supported by reinforcing walls 99 (see Figure 45).
Furthermore, each of the larger segments 88 has a rein-
10 forcing wall 98 and a reinforcing wall 99 constituting an
integral part thereof. Therefore, there is complete
bracing transversely across the cartridge assembly 66
against any transverse compressive forces. It will be
noted from Figure 63 that the support plate 126 is
15 located above sliders 113 and 114 and, therefore, cannot
interfere with their operation.

Reference is now made to Figures 22 and 52-57,
wherein indexing button 162 is illustrated. Indexing
button 162 comprises a U-shaped member having an arcuate
20 base portion 163 terminating in parallel leg portions 164
and 165. Leg portion 164, itself, terminates in a thin
leg portion 166, while leg portion 165 similarly termi-
nates in a thin leg portion 167. Leg portions 166 and
167 are also parallel and are coextensive.

25 On its exterior surface, the leg portion 166 carries
an integral indicator 168 extending transversely thereof.
The exterior surface of leg portion 167 carries an identi-
cal indicator 169 extending transversely thereof and
aligned with indicator 168.

30 To complete the structure of indexing button 162, leg
portion 166 has an integral lug 170 extending downwardly
from its inside surface. Leg portion 167 also has a lug
171 extending downwardly from its inside surface. As is
most clearly seen in Figures 55 and 56, the free ends of
35 lugs 170 and 171 are enlarged so as to present abutment

1 surfaces 170a and 171a facing away from indexing button
base portion 163. Abutment surfaces 170a and 171a are
intended to contact the ends of sliders 113 and 114,
respectively, so that the indexing button can be used to
5 shift or index the sliders simultaneously. It will be
noted from Figures 52-55 that the lug 70 is of a lesser
transverse length than the lug 171. This takes into
account the difference in lengths of the sliders 113 and
114.

10 Figures 58, 59 and 63 illustrate indexing button 162
mounted in cartridge assembly 66. In all of these Fig-
ures, the indexing button is shown in its normal, unactu-
ated position. It will be noted that the base portion
163 and the majority of leg portions 164 and 165 extend
15 beyond the confines of cartridge 71 and casing 140
through the notch 150 in the rounded end 144 of casing
140. Thin leg portions 167 and 166 of indexing button
162 are supported by cartridge cam elements 80 and 79,
respectively. Downwardly depending lug 170 lies along
20 the inside surface portion 101 of cartridge wall 74 (see
also Figure 24). Similarly, the downwardly depending lug
171 of indexing button 162 lies along the inside surface
portion 102 of cartridge wall 74. The indexing button
lugs 170 and 171 also abut the inside surface portion 100
25 of cartridge wall 74. Since indexing button 162 is sub-
stantially U-shaped, it will be understood that it will
not interfere with cartridge perforation 81 or alignment
and retaining pin 69 extending therethrough. The abut-
ment surfaces 170a and 171a are located adjacent the ends
30 of sliders 113 and 114, respectively.

The large notch 151 of casing side 141 serves as a
window through which indexing button indicator 168 can be
easily viewed. Similarly, the large notch 162 in the
casing side 142 serves as a window through which indexing
35 button indicator 169 can be viewed. Either the casing

140 or the cartridge 71 can be provided with indicia cooperating with indexing button indicators 168 and 169. For purposes of an exemplary showing, the cartridge portion of cartridge assembly 66 is shown (in Figure 21) provided with the numerals "1" and "2". As shown in Figure 21, when the indexing button 162 is in its normal, unactuated position, its indicator 169 will align with the numeral "1" on the cartridge. The same sort of indicia may be provided on the other side of the cartridge to cooperate with indicator 168.

It will be apparent from Figures 58, 59 and 63 that if indexing button 162 were shifted in the direction of arrow B in Figure 59, the abutment surfaces 170a and 171a would engage the ends of sliders 113 and 114, causing them to index as described above. As will be apparent from Figure 45, when sliders 113 and 114 are indexed, the ends opposite those ends contacted by abutment surfaces 170a and 171a of indexing button 162 will abut the inside surface portions 105 and 106 of cartridge wall 74 to prevent over-indexing. Furthermore, support plate shoulders 131 and 132 act as stop surfaces for indexing button 162. Returning to Figure 21, once indexed, the indicator 169 will align with the numeral "2" on cartridge 71, the same being true of indexing button indicator 168. This is a clear visual indication to the surgeon that the second load of staples has been shifted from the storage pockets to the forming pockets of cartridge 71 and are ready for implanting and forming by a second actuation of instrument 60.

The cartridge assembly 66 is completed by safety 172 illustrated in Figures 22 and 60-62. The purpose of safety 172 is to prevent indexing of indexing button 102 and sliders 113 and 114 when staples are still present in forming pockets 93 and 95. In this way, proper sequencing of the cartridge assembly 66 is assured and jamming

1 is precluded.

5 The safety 172 comprises an elongated shank 173 of uniform width and thickness terminating at its upper end, as viewed in Figures 61 and 62 in an enlarged portion 174. At its lower end, the shank 173 terminates in an enlarged portion 175, somewhat larger than the enlarged end 174. The enlarged end 175 provides an abutment surface 176 intended to cooperate with the abutment surface 171a of lug 171 on indexing button 162.

10 Safety 172 is shown in its normal position within cartridge assembly 66 in Figure 63. It will be noted that the shank portion 173 extends through the support plate 126 at the juncture of end wall 129 and lug 138b of narrow side wall portion 128a (see also Figure 41). The enlarged end 175 is located just beneath support plate 126 while the enlarged end 174 is located beneath a shoulder 107a of driver 107 (see also Figures 34 and 35). When safety 172 occupies the position shown in Figure 63, its abutment surface 176 faces abutment surface 171a of indexing button 162 and precludes movement thereof.

20 The bottom 73 of cartridge 71 is provided with a perforation 177 so sized as to just nicely receive the enlarged end 175 of safety 172. It will be apparent from Figure 63 that when the instrument is actuated for a first time, causing driver 107 to shift downwardly and to implant and form the staples 93a and 95a in forming pockets 93 and 95, the shoulder 107a of driver 107 will contact the uppermost surface of the enlarged safety end 174, causing the safety 172 to shift downwardly. This will cause the enlarged end 175 of the safety 172 to enter the perforation 177 in cartridge 71, clearing the way for indexing of indexing button 162 and sliders 113 and 114, as soon as driver 107 is returned to its normal retracted position. The downwardmost position of safety 35 172 is determined by the abutment of its upper enlarged

end 174 against the top surface of support plate 126.

The cartridge assembly 66 of the present invention, having been described in detail, its operation may now be set forth. In the particular embodiment shown, the cartridge assembly 66 comprises a permanent part of instrument 60. When the surgeon receives instrument 60, it will be in the condition shown in Figure 21 with the cartridge assembly 66 spaced from anvil 65 and the alignment and retaining pin 69 in its retracted position. The surgeon locates the tissue to be sutured between the cartridge assembly 66 and the anvil 65, and then shifts the alignment and retaining pin 69 to its operating position by handle 70. In this position, the alignment and retaining pins 69 extends through the cartridge assembly 66 and into a suitable perforation in fixed jaw 64, trapping the tissue to be sutured between anvil 65 and cartridge assembly 66.

This having been accomplished, the surgeon next sets the gap or distance between the cartridge assembly 66 and the anvil 65, within the working gap of the instrument, in accordance with the procedures set forth in the above noted co-pending application. Thereafter, trigger 63 is actuated, causing driver 107 to shift the staples 93a and 95a in forming pockets 93 and 95 through the tissue and against the anvil 65, thus implanting and clinching these staples to form a double, staggered row of staple sutures. This having been done, the cartridge assembly 66 is shifted to its retracted position, as is alignment and retaining pin 69, and the instrument is removed from the sutured tissue.

As indicated above, the first actuation of driver 107 will simultaneously shift cartridge assembly safety 172 from its disabling to its enabling position. The surgeon is now free to push indexing button 162 with respect to assembly 166, thus indexing sliders 113 and 114 and

1 shifting surgical staples 91a and 94a from holding
pockets 91 and 94 to forming pockets 93 and 95. Indexing
button indicators 168 and 169 will show that this has
5 been done and that the instrument is ready for a second
use. At this point, the stapling procedure just
described can be repeated. After the second actuation of
the instrument 60, the instrument, together with the cart-
ridge assembly 66, is disposed of.

10 While the cartridge assembly 66 may be appropriately
constructed for refilling and reuse, it lends itself well
to manufacture as a single-use, disposable unit. The
various parts illustrated in Figure 22 can be molded of
plastic material suitable for a surgical environment and
capable of being sterilized by autoclave, ethylene oxide,
15 irradiation, or other standard methods.

In the embodiments thus far described, when the surgi-
cal staples in the forming pockets have been formed and
implanted, at least a second set of staples is introduced
into the forming pockets directly from storage pockets,
20 or from staging pockets located between the forming
pockets and the storage pockets. It is within the scope
of the invention to provide an embodiment of the cart-
ridge assembly wherein, after the first set of staples in
the forming pockets have been implanted and formed, the
25 forming pockets are moved from the line of action between
the driver and the anvil, and the storage pockets, con-
taining a second set of surgical staples, are shifted
into the line of action between the driver and the anvil,
thus becoming forming pockets. This arrangement is illus-
30 trated in simplified, diagrammatic form in Figures 65-68.

Reference is first made to Figure 65, wherein a cart-
ridge assembly is generally indicated at 178. The anvil
of a linear surgical stapling instrument is diagrammati-
cally indicated at 179. The magazine assembly 178 com-
35 prises a body 180 and a plunger-like element 181

1 shiftable transversely with respect to body 180. The
plunger-like element 181 contains a row of forming
pockets, the endmost one of which is shown at 182. The
plunger-like element 181 contains a row of storage
5 pockets, the endmost one of which is shown at 183. Each
of the forming pockets and each of the storage pockets is
provided with a surgical staple. A surgical staple 184
is shown in endmost forming pocket 182 and a surgical
staple 185 is shown in endmost storage pocket 183. The
10 number of storage pockets is equal to the number of
forming pockets.

The cartridge assembly 178 has a driver 186. The
driver 186 is provided with a plurality of blades equal
in number to the number of forming pockets. The endmost
15 driver blade is shown at 187. The body 180 has a slot
for each driver blade. The endmost slot for driver blade
187 is shown at 188. To complete the diagrammatic repre-
sentation of Figure 65, the plunger-like element 181 is
provided with a handle-like element 189, representing an
20 indexing mechanism.

Figure 65 illustrates the cartridge assembly 178 in
its initial, fully loaded condition. It will be under-
stood that the cartridge assembly 178 will be mounted on
a linear surgical stapling instrument (not shown). The
25 operation of the cartridge assembly 178 will be described
in terms of forming pocket 182, storage pocket 183 and
staples 184 and 185. It will be understood that pre-
cisely the same things will occur in all of the forming
pockets and storage pockets.

30 When the linear surgical stapling instrument (not
shown) is actuated for a first time, the driver 186 will
shift downwardly as viewed in Figure 65 to the position
shown in Figure 66. This will drive the staple 184 from
forming pocket 182, through tissue (not shown) located
35 between the cartridge assembly 178 and the anvil 179, and

1 will cause the staple 184 to be formed by anvil 179.

After the first actuation of the linear surgical stapling instrument, the driver 186 is withdrawn to its normal retracted position, as shown in Figure 67. At
5 this point, the indexing mechanism 189 is used to shove the plunger-like element 181 to the left as viewed in Figures 65-68, to the position shown in Figure 67. This movement of the plunger-like member 181 shifts the forming pocket 182 from the line of action between driver 186
10 and anvil 179. This, of course, is true of all of the forming pockets. Simultaneously, storage pocket 183 (and all of the other storage pockets) are shifted into the line of action between the driver 186 and anvil 179. This is illustrated in Figure 67. It will be seen from
15 Figure 67 that with the plunger-like element 181 in the position shown, the storage pocket 183 (and the other storage pockets), in essence, become or are converted to forming pockets.

At this point, the linear surgical stapling instrument can be actuated for a second time. This will cause
20 staple 185 of pocket 183 to be driven from pocket 183 (and all of the other staples to be driven from the equivalent pockets), through tissue (not shown) between the cartridge assembly 178 and the anvil 179, and to be
25 clinched by the anvil 179. This is shown in Figure 68.

The cartridge assembly 178 of Figures 65-68 constitutes a simple example of a two-load cartridge assembly. It will be understood that the plunger-like element 181 could be provided with additional rows of storage
30 pockets, each row (in its turn) being shiftable into the line of action between driver 186 and anvil 179.

In the embodiment just described, the forming pocket 182 (and the other forming pockets therebehind) and the storage pocket 183 (and the other storage pockets there-
35 behind) are shifted in a rectilinear path of travel. It

1 will be understood that other paths of travel could be
used. To illustrate this, reference is made to the
embodiment of Figure 69.

5 In Figure 69, a cartridge assembly is generally
indicated at 190, together with an anvil 191. The cart-
ridge assembly 190 comprises a body 192 and a member 193
rotatable with respect thereto. The member 193 is pro-
vided with a row of forming pockets, the endmost one of
10 which is shown at 194. The member 193 is provided with
one or more rows of storage pockets. For purposes of an
exemplary showing, the member 193 is shown as having two
rows of storage pockets, the endmost storage pocket of
each row being shown at 195 and 196, respectively. Each
forming pocket and each storage pocket is provided with a
15 surgical staple. To this end, forming pocket 194 is
shown provided with a surgical staple 197. Storage
pockets 195 and 196 are shown provided with surgical
staples 198 and 199, respectively. Again, it will be
understood that the number of storage pockets in each row
20 thereof will be equal and will be equal to the number of
forming pockets.

A driver is illustrated at 200. The driver will have
a blade for each forming pocket. The endmost blade of
driver 200 is shown at 201. The body 192 of cartridge
25 assembly 190 will have slots formed therein equal in
number to the driver blades and adapted to slidably
receive the driver blades. The endmost slot of body 192
is indicated at 202. Finally, to complete the cartridge
assembly 190 of Figure 69, the member 193 is shown as
30 having a handle-like element 203, diagrammatically repre-
senting an indexing means.

Again, it will be understood that the cartridge assem-
bly 190 will be affixed to an appropriate linear surgical
stapling instrument (not shown). In Figure 69, the cart-
35 ridge assembly is illustrated in its initial, fully

1 loaded condition. Upon a first actuation of the linear
surgical stapling instrument, the driver 200 will shift
the staple 197 of forming pocket 194 out of forming
5 pocket 194, through tissue (not shown) located between
the cartridge assembly 190 and the anvil 191, and will
cause the clinching of staple 197 by anvil 191. It will
be understood that surgical staples located in the other
forming pockets (not shown) will be similarly implanted
and formed.

10 Thereafter, the driver 200 is returned to its normal
position illustrated in Figure 69 and the indexing ele-
ment 203 may be used to rotate member 193 so that the row
of forming pockets represented by forming pocket 194 will
be shifted out of the line of action between driver 200
15 and anvil 191, and the row of storage pockets, repre-
sented by storage pocket 195, will be shifted into the
line of action between driver 200 and anvil 191, becoming
the equivalent of forming pockets. The linear surgical
stapling instrument (not shown) can now be actuated for a
20 second time, and the driver 200 will cause the row of
staples represented by staple 198 to be shifted from
storage pockets represented by storage pocket 195 through
tissue (not shown) located between cartridge assembly 190
and anvil 191, and to be clinched or formed by the anvil
25 191.

At this stage, the driver 200 can again be returned
to its normal position shown in Figure 69 and the index-
ing element 203 can be used to cause the member 193 to
rotate again, shifting the row of storage pockets repre-
30 sented by storage pocket 195 out of the line of action
between driver 200 and anvil 191 and locating the storage
pockets represented by storage pocket 196 within this
line of action. The storage pockets represented by stor-
age pocket 196 thus become the equivalent of forming
35 pockets.

1 At this point, the surgical stapling instrument can
again be actuated. This will result in the driver 200
shifting the staples represented by staple 199 from the
storage pockets represented by storage pocket 196,
5 through tissue (not shown) located between the cartridge
assembly 190 and anvil 191, causing these staples to be
clinched or formed by the anvil 191.

10 In the embodiment of Figure 69, as is true of the
embodiment of Figures 65-68, the number of rows of stor-
age pockets does not constitute a limitation. In the
embodiment of Figures 65-68 and the embodiment of Figure
69, safety interlocks and load counting means have been
omitted for purposes of clarity. It will be understood
that such elements could, and preferably would, be pro-
15 vided with each embodiment. Both embodiments could con-
stitute disposable cartridge assemblies, reusable and
refillable cartridge assemblies, or could be incorporated
into a completely disposable instrument. As was
described with respect to the embodiments of Figures
20 5-20, efficient design of the cartridge assemblies would
allow for single inputs from the surgeon via the linear
surgical stapling instrument to result in several motions
within the cartridge. Again, some form of stored energy
source could be associated with the cartridge assemblies
25 to partially or fully operate them. In all of the embodi-
ments of Figures 1-20 and Figures 65-69, the driver, or
the anvil, or both, could constitute a part of the mul-
tiple load cartridge assembly, itself.

30 In the above description, terms such as "top",
"bottom", "upper", and "lower", are used in conjunction
with the drawings for purposes of clarity. One skilled
in the art will understand that during use, the instru-
ment 60 may assume any desired or required orientation.

35 Modifications may be made in the invention without
departing from the spirit thereof.

1 WHAT IS CLAIMED IS:

1. A surgical stapling instrument for implanting staples in tissue, comprising:

anvil means;

5 means for driving staples against said anvil means;

a first array of staples located in a first position within said instrument aligned between said driving means and said anvil means;

10 a second array of staples located in a second position within said instrument out of alignment with said driving means and said anvil means;

means for actuating said driving means to move an array of staples from said first position and clinch said array of staples against said anvil means; and

15 means for transferring said second array of staples from said second position to said first position after a first operation of said actuating means to enable a second operation of said actuating means.

20 2. The instrument of claim 1, further comprising first storage means for storing an array of staples at said first position and second storage means for storing an array of staples at said second position.

25 3. The instrument of claim 1, wherein said transfer means comprises means for individually shifting each of the staples contained in said second array from said second position to said first position.

30 4. The instrument of claim 2, wherein said transfer means includes means for indexing said first storage means out of said first position while indexing said second storage means from said second position to said first position.

35 5. The instrument of claim 2, wherein said first storage means comprises a plurality of forming pockets and said second storage means comprises a plurality of

1 storage pockets.

6. The instrument of claim 5, wherein each of said storage pockets corresponds to a forming pocket and is located adjacent thereto.

5 7. The instrument of claim 6, wherein said first array of staples includes one staple in each of said forming pockets and said second array of staples includes at least one staple in each of said storage pockets.

10 8. The instrument of claim 7, wherein said transfer means includes means for indexing a staple from each of said storage pockets to its corresponding forming pocket after each operation of said actuating means.

15 9. The instrument of claim 1, further comprising safety means for preventing a second operation of said actuating means before operation of said transfer means.

10. The instrument of claim 5, wherein said forming pockets are arranged in at least two rows which are longitudinally staggered.

20 11. The instrument of claim 4, further including third storage means for storing a third array of staples at a third position, and fourth storage means for storing a fourth array of staples at a fourth position.

25 12. The instrument of claim 11, wherein said transfer means further includes means to ultimately index each of said storage means to said first position.

13. The instrument of claim 12, further including means for indicating which of said storage means is in said first position.

30 14. The instrument of claim 1, including means for indicating which of said array of staples is positioned in said first position.

15. A surgical stapling instrument for simultaneously implanting a plurality of staples in tissue, comprising:

35 anvil means;

1 means for driving staples against said anvil
means;

first cartridge means for holding a plurality of
staples in a first position aligned between said driving
5 means and said anvil means;

second cartridge means for holding a plurality
of staples in a second position out of alignment with
said driving means and said anvil means;

means for actuating said driving means to move
10 said staples from said first cartridge means and clinch
said staples against said anvil means; and

means for indexing said second cartridge means
from said second position to said first position, after a
first operation of said actuating means, to enable a
15 second operation of said actuating means.

16. The instrument of claim 15, wherein said first
and second cartridge means are contained within a unitary
cartridge assembly.

17. The instrument of claim 16, wherein said cart-
20 ridge assembly is removably mounted on said instrument.

18. The instrument of claim 16, wherein said instru-
ment comprises a disposable instrument.

19. The instrument of claim 17, wherein said cart-
ridge assembly is disposable.

20. The instrument of claim 17, wherein said cart-
25 ridge assembly may be removed from said instrument,
refilled with staples and replaced in said instrument,
allowing said cartridge assembly to be reused.

21. The instrument of claim 15, further including
30 means for indicating which of said cartridge means is
located at said first position.

22. A surgical stapling instrument for forming and
implanting at least one row of surgical staples in
tissue, comprising:

35 a frame terminating at its forward end in a

- 1 fixed jaw;
an anvil mounted on said fixed jaw;
a cartridge assembly, slidably supported by said
frame and shiftable longitudinally thereon, containing at
5 least one row of forming pockets, each of which contains
a staple, and a plurality of staple-carrying staging pockets,
each of which is coupled to a corresponding forming pocket;
means slidably mounted within said cartridge
10 assembly for driving said staples from said forming pockets
against said anvil;
means for actuating said staple driving means
between a retracted position and a staple driving position;
and
15 means for transferring a staple from each of
said staging pockets to its corresponding forming pocket
after a first operation of said actuating means, to
enable another operation of said actuating means.
23. The instrument of claim 22, wherein said cartridge
20 means further includes a plurality of storage pockets,
coupled to each of said staging pockets, for storing
at least one staple in each pocket thereof.
24. The instrument of claim 23, further including
second transfer means for moving a staple from each of
25 said storage pockets to its corresponding staging pocket
upon operation of said first transfer means.
25. The instrument of claim 22, wherein said anvil,
said staple driving means and said cartridge assembly
comprise a disposable unit which is removably mounted on
30 said frame.
26. The instrument of claim 22, wherein said cartridge
assembly is removably mounted on said frame, and
said pockets thereof are capable of being refilled with
staples.
- 35 27. The instrument of claim 22, wherein said forming

1 pockets are arranged in at least two rows which are longi-
tudinally staggered.

28. The instrument of claim 24, wherein said first
and second transfer means operate simultaneously.

5 29. The instrument of claim 22, further comprising
safety means for preventing operation of said indexing
means when staples are present in said forming pockets.

30. The instrument of claim 22, wherein said anvil
and said cartridge assembly comprise a disposable unit
10 which is removably mounted on said frame.

31. The instrument of claim 22, further comprising
means for indicating that said transfer means has oper-
ated.

32. A linear surgical stapling instrument for simul-
15 taneously forming and implanting at least one row of sur-
gical staples in tissue, comprising:

anvil means;

means for driving staples against said anvil
means;

20 cartridge means for holding a plurality of
staples, said cartridge means containing a first set of
pockets aligned between said driving means and said anvil
means and a second set of pockets coupled to each of said
first pockets, wherein each of said pockets contains a
25 staple;

means for actuating said driving means to move
said staples from said first set of pockets of said cart-
ridge means and clinch said staples against said anvil
means; and

30 means for transferring said staples from said
second set of pockets to said first set of pockets, after
a first operation of said actuating means, to enable a
second operation of said actuating means.

33. The instrument of claim 32, wherein said first
35 set of pockets is arranged in at least two staggered

1 . rows.

34. The instrument of claim 32, wherein said cartridge means comprises a disposable unit which is removably mounted on said instrument.

5 35. A multiple load cartridge for use in a surgical stapling instrument having anvil means for simultaneously implanting a plurality of surgical staples in tissue, comprising:

means for driving staples against said anvil
10 means;

cartridge means for holding a plurality of staples, said cartridge means containing a first set of pockets aligned between said driving means and said anvil means and a second set of pockets corresponding to each
15 of said first pockets, wherein each of said pockets contains a staple;

means for actuating said driving means to move
said staples from said first set of pockets and clinch
said staples against said anvil means to implant said
20 staples in tissue;

first means for indexing said first set of pockets out of alignment with said driving means and said anvil means; and

second means for indexing said second set of
25 pockets into alignment between said driving means and said anvil means, after operation of said actuating means and said first indexing means, whereby a second operation of said actuating means is enabled.

36. The assembly of claim 35, wherein said driving
30 means and said cartridge means are contained in a unitary cartridge assembly which is removably mounted on said surgical stapling instrument.

37. The assembly of claim 36, wherein said unitary cartridge assembly is disposable.

35 38. The assembly of claim 36, wherein said unitary

1 cartridge assembly comprises a reusable unit which may be
refilled with staples.

39. A multiple-load cartridge assembly for use with
a linear surgical stapling instrument of the type having
5 an anvil and a staple driver actuator which, when actuated, simultaneously implants at least one row of surgical staples in the tissue of a patient and clinches said surgical staples of said at least one row against said anvil, said cartridge assembly comprising a cartridge
10 having at least one row of staple-containing forming pockets, a driver mounted within said cartridge assembly and shiftable therein by said driver actuator between a retracted position and an extended position, said driver having a plurality of blades equal in number to the number of said forming pockets and configured to enter said
15 forming pockets and drive said staples therein through said tissue and against said anvil when shifted from said retracted position to said extended position by operation of said staple driver actuator, said cartridge assembly
20 having a plurality of storage pockets equal in number to said forming pockets and each containing at least one staple and an indexing means to shift said at least one staple in each storage pocket to the adjacent one of said forming pockets to reload said forming pockets after the
25 first operation of said staple driver actuator.

40. The cartridge assembly claimed in claim 39, including a safety means to disable said indexing means until said forming pockets are emptied by said driver.

41. The cartridge assembly claimed in claim 39,
30 having at least two staggered rows of staple-containing forming pockets and a staple-containing storage pocket for each of said forming pockets.

42. The cartridge assembly claimed in claim 39, including visual indicator means showing the number of
35 the load of surgical staples in said forming pockets.

1 43. The cartridge assembly claimed in claim 39,
including an equal number of surgical staples, greater
than one, in each of said storage pockets, and including
a staging pocket between each storage pocket and its
5 respective forming pocket, said indexing means comprising
a first indexer to shift a staple from each storage
pocket to its respective staging pocket when empty and a
second indexer to shift a staple from each staging pocket
to its respective forming pocket to reload said forming
10 pocket after each operation of said driver actuator.

 44. The structure claimed in claim 39, including an
equal number of surgical staples, greater than one, in
each of said storage pockets, said indexing means being
capable of shifting a staple from each of said storage
15 pockets to its respective forming pocket after each opera-
tion of said driver actuator to introduce a staple load
into said forming pockets.

 45. The structure claimed in claim 41, including an
equal number of surgical staples, greater than one, in
20 each of said storage pockets, said indexing means being
capable of shifting a staple from each of said storage
pockets to its respective forming pocket after each opera-
tion of said driver actuator to introduce a staple load
into said forming pockets.

25 46. A multiple load cartridge assembly for use with
a linear surgical stapling instrument of the type having
an anvil and a staple driver actuator which, when actu-
ated, simultaneously implants at least one row of surgi-
cal staples in the tissue of a patient and clinches said
30 surgical staples of said at least one row against said
anvil, said cartridge assembly comprising a driver
mounted within said cartridge assembly and shiftable
therein by said driver actuator between a retracted posi-
tion and an extended position, a cartridge having at
35 least one row of staple-containing first pockets at a

1 first position aligned between said driver and said
anvil, said driver having a plurality of blades equal in
number to the number of said first pockets and configured
to enter said first pockets and drive said staples
5 therein through said tissue and against said anvil when
shifted from said retracted position to said extended
position by operation of said staple driver actuator,
said cartridge assembly having a plurality of second
pockets at a second position equal in number to said
10 first pockets and each containing at least one staple,
and indexing means to shift said plurality of first pockets
out of said first position and said plurality of said
second pockets into said first position after the first
operation of said staple driver actuator to enable a
15 second operation of said actuator.

47. The cartridge assembly claimed in claim 46,
including a safety means to disable said indexing means
until said first pockets are emptied by said driver.

48. A method of applying a plurality of surgical
20 staples to tissue with a surgical stapling instrument of
the type having a fixed jaw supporting an anvil, a movable
jaw, a multiple load staple cartridge coupled to
said movable jaw, a staple driver, and means for actuating
said staple driver, comprising the steps of:

25 (a) positioning said tissue to be stapled
between said anvil and said staple cartridge located on
said movable jaw, said cartridge containing a first array
of staples located in a first position within said cartridge
aligned between said anvil and said driver, and a
30 second array of staples located in a second position
within said cartridge out of alignment with said anvil
and said staple driver;

(b) adjusting said movable jaw toward said
anvil so that said cartridge is spaced at a distance from
35 said anvil such that said staples will be properly

clinched against said anvil;

(c) operating said staple driver to drive said first array of staples from said first position in said cartridge through said tissue and against said anvil;

(d) adjusting said movable jaw away from said stapled tissue;

(e) releasing said stapled tissue from between said jaws of said instrument;

(f) operating an indexing means to transfer said second array of staples from said second position to said first position;

(g) repeating steps (a) through (e).

49. The method of claim 48, wherein the indexing step further includes the step of individually shifting each of said staples contained in said second array from said second position to said first position.

50. The method of claim 48, wherein the indexing step further includes the step of simultaneously shifting all of said staples contained in said second array from said second position to said first position.
